

### Program Office Technology Management Process

#### Dominic Benford

Chief Scientist, Cosmic Origins Program Office

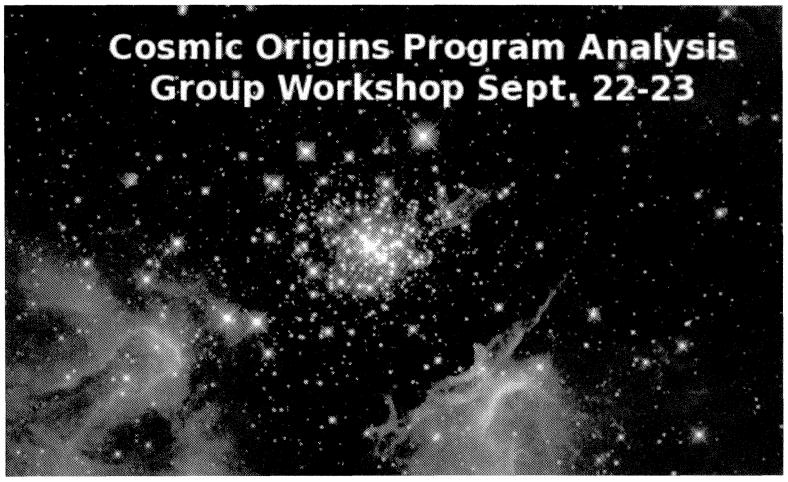

COPAG Workshop September 22, 2011

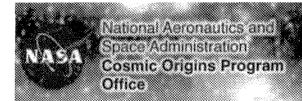

# COPAG Workshop

#### Why are we here?

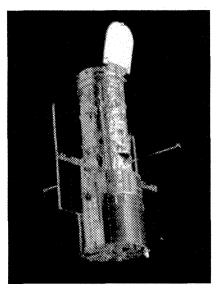

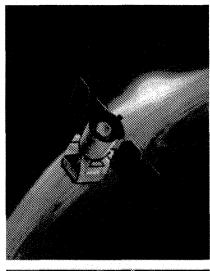

## Science Portfolio

#### Already

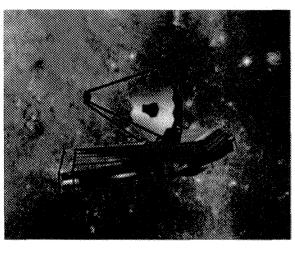

Upcoming

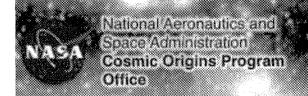

Possibles: Recommended by

Decadal Survey

et alia...

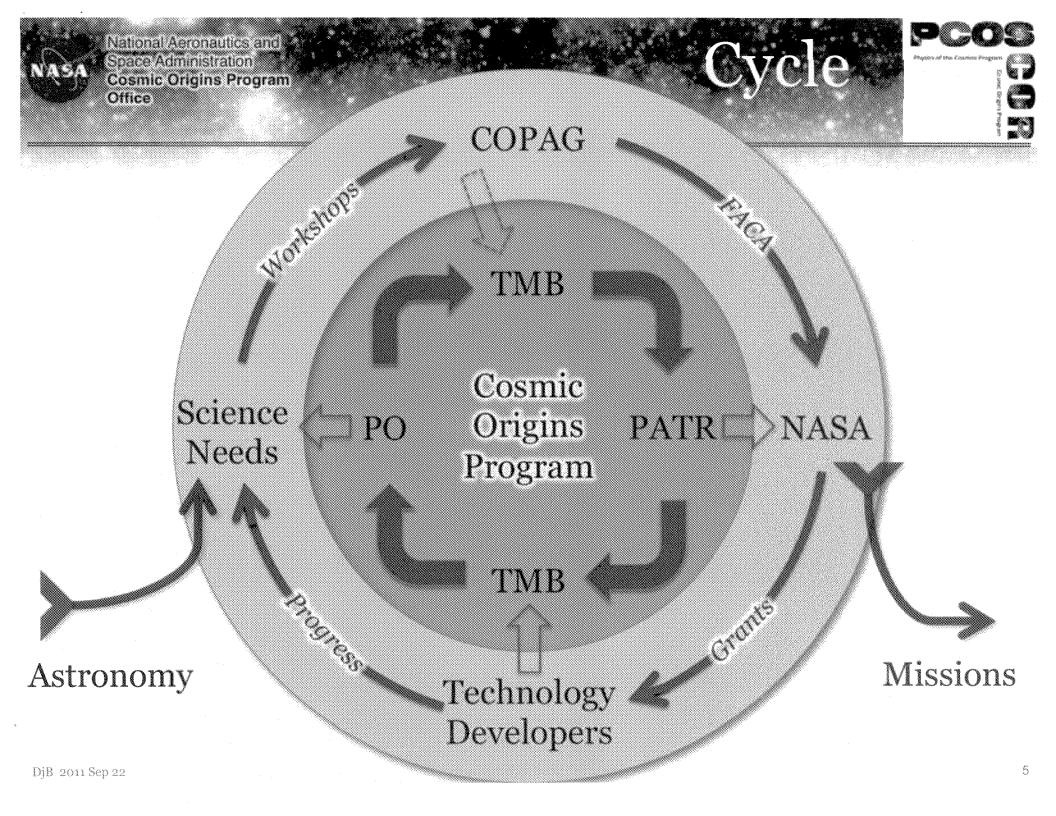

### Technology

 Program Office implements technology maturation, inheriting needs from the broadest community

Stakeholders identify science needs

COPAG = formal introduction mechanism

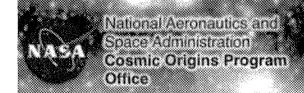

#### What Next?

- Technology Management Board (TMB):
  - Reviews Program's technology needs and recommends priorities.
  - Provides input to Program technology development activities and planning.
  - Reviews proposed Technology Development Plans; approves milestones.

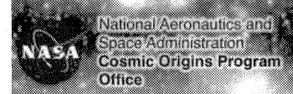

Mansoor Ahmed, Dominic Benford, Allan Cohen, Chris Davis, Richard Griffiths, Beth Keer, Mike Moore, Mario Perez, Thai Pham, Jackie Townsend

# SAT/COR FY12

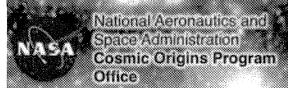

Proposal Title		Institution	Area
Advanced UVOIR Mirror Technology Development for Very Large Space Telescopes	Phillip Stahl	Marshall Space Flight Center	Advanced, Normal Incidence Optics
High performance cross-strip micro-channel plate detector systems for spaceflight experiments	John Vallerga	UC Berkeley	Detectors
Enhanced MgF2 & LiF Overcoated Al Mirrors for FUV Space Astronomy	Manuel Quijada	Goddard Space Flight Center	Ultraviolet Coatings

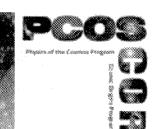

# Starting Point

High QE, low noise, large- format UV photon counting detectors	UV coatings	Large, low-cost, light-weight precision mirrors for Ultra- Stable Large Aperture UV/Optical Telescopes	Large format, low noise Far-IR direct detectors	Large, cryogenic far-IR telescopes	Sub-Kelvin Coolers
Future NASA UV missions, particularly those devoted to spectroscopy, require high quantum efficiency (>50%), low noise (<1e-7 ct/pixet/s), largeformat (>2k x 2k) photon-counting detectors	High reflectivity, highly uniform UV coatings are required to support the next generation of UV missions, including explorers, medium missions, and a UV/optical large mission. High reflectivity coatings allow multiple reflections, extended bandpasses, and accommodate combined UV and high-contrast exoplanet imaging objectives.	Future UV/Optical telescopes will require increasingly large apertures to answer the questions raised by HST, JWST, Ptanck and Hershel, and to complement the ≥ 30-m ground-based telescopes that will be coming on line in the next decade.  For diffraction limited performance, the pointing budget gets tighter as aperture grows and wavelengths shrink, requiring θ ~ 0.1 λ/D pointing accuracy. Technologies are therefore required that provide a high degree of thermal and dynamic stability, and wave front sensing and control	Future NASA Far-IR missions require large format detectors optimized for the very low photon backgrounds present in space.  Arrays containing up to tens of thousands of pixels are needed to take full advantage of the focal plane available on a large, cryogenic telescope. Detector sensitivity is required to achieve background-limited performance, using direct (incoherent) detectors to avoid quantum-limited sentivitiy.	Large telescopes provide both light gathering power, to see the faintest targets, and spatial resolution, to see the most detail and reduce source confusion. To achieve the ultimate sensitivity, their emission must be minimized, which requires that these telescopes be operated at temperatures that, depending on the application, have to be as low as 4K. Collecting areas on the order of 10m are needed.	Optics and detectors for far-IR and certain X-ray missions require very low temperatures of operation, typically well below 1K. Compact, low-power, lightweight coolers suitable for space flight are needed to provide this cooling
The goal is to produce large- format, high QE, low-noise UV- sensitive detectors routinely that can be employed in a variety of explorer, medium, and strategic missions.	Development of UV coatings with high reflectivity (>90-95%), high uniformity (<1-0.1%), and wide bandpasses (~100 nm to 300-1000 nm). New coating technologies such as Atomic Layer Deposition are particularly promising. Some will be required for large optics (0.5-4m), many for smaller instrument optical elements.	Develop lightweight UV and optical mirrors with  Areal density <20kg/m2, surface roughness 5 to 10 nm rms, cost <\$2M/m2, for telescopes with > 50 m2 aperture,<1 mas pointing accuracy, and  < 15 nm rms stability	Detector sensitivities with noise equivalent powers of 10 ° W/\Hz are needed for photometry, and ≈3·10·2¹ W/\Hz are needed for spectroscopy.	The goal is to develop a feasible and affordable approach to producing a 10m-class telescope with sufficiently high specific stiffness, strength, and low areal density to be launched, while maintaining compatibility with cryogenic cooling and far-IR surface quality/figure of ~1µm RMS.	A cryocooler operating from a base temperature of ~4K and cooling to <0.1K with a continuous heat lift of 10µW is required for several mission concepts. Features such as compactness, low power, low vibration, intermediate cooling and other impact-reducing design aspects are desired.
